

Task2Points

Setup & Installation Guide — Gamified Daily Tasks Web App

Overview

Task2Points is a full-stack web application where users complete daily tasks — either auto-graded quizzes or photo-verified real-world activities — to earn XP, unlock achievements, level up, and compete on a leaderboard. This guide explains how to view the live version, and how to run the full project locally.

Tech stack: React + Vite + Tailwind CSS (frontend), Node.js + Express (backend), PostgreSQL + Prisma ORM (database), JWT authentication.

Option 1: View the Live Version (No Installation Needed)

The fastest way to review this project is through its live, deployed version — no setup required.

Live website	https://task2points.vercel.app
Source code (GitHub)	https://github.com/SHIBEGGGG/Task2Points
Admin login	<code>admin@example.com</code> / <code>Admin123!</code>

Log in with the admin account above to review the task/quiz management console and the photo-submission review queue, or register a new account to try the app as a regular user.

Option 2: Run the Project Locally

Use this if you'd like to inspect or run the code directly on your own computer.

Prerequisites

- Node.js 18 or later (includes npm) — nodejs.org
- Git — git-scm.com
- A code editor, e.g. Visual Studio Code
- A PostgreSQL database — either installed locally, or a free hosted instance (e.g. neon.tech, which this project's live version uses)

Step 1: Clone the repository

Open a terminal in the folder where you want the project, then run:

```
git clone https://github.com/SHIBEGGGG/Task2Points.git
cd Task2Points
```

Step 2: Set up the database connection

Create a PostgreSQL database (locally, or via a free provider like Neon or Supabase). Then copy the example environment file and fill in your real values:

```
cd server
copy .env.example .env      (Windows)
cp .env.example .env        (Mac/Linux)
```

Note: Open the new .env file and set DATABASE_URL to your database's connection string, and JWT_SECRET to any long random string.

Step 3: Install backend dependencies and set up the database schema

From inside the server folder:

```
npm install
npx prisma generate
npx prisma db push
npm run seed
```

Step 4: Start the backend server

Still inside server:

```
npm run dev
```

Note: The backend runs at <http://localhost:4000> by default. Visit <http://localhost:4000/api/health> in a browser — it should return `{"status": "ok"}`.

Step 5: Set up and start the frontend

Open a second terminal, then:

```
cd client
copy .env.example .env      (Windows)
cp .env.example .env        (Mac/Linux)
npm install
npm run dev
```

Note: Make sure `client/.env`'s `VITE_API_URL` points to <http://localhost:4000/api> for local use.

Step 6: Open the app

Visit <http://localhost:5173> in a browser. Register a new account, or log in with the seeded admin account (admin@example.com / Admin123!) to access the admin console.

Project Structure

client/ — React + Vite + Tailwind frontend | **server/** — Node.js + Express backend | **server/prisma/** — database schema and seed data

For a full breakdown of features, API routes, and project architecture, see the [README.md](#) file in the repository root.
